How often do you consider the emotional state of your electrons? Most likely you view electrons as useful but utterly expendable. You probably don't give them individual names or even numbers instead referring to them en-mass as 1 nC or, worse yet not even acknowledging the time at which they expend their last full measure, as 1 nA. My recent studies have uncovered that electrons have had enough of being disparaged as indistinguishable. All electrons may all share the same charge, mass and intrinsic angular momentum but, deep in their hidden variables, they long to express their own unique personal identity. What is more they will perform better – produce sharper patterns with better contrast – with a little encouragement and personal acknowledgment. It's not much to ask but the time has come for a little individual respect for the humble, hard-working electron.
